Notes: “Not Available” indicates that not enough data were available to calculate the measure. For CLABSI and Colon SSI the locally measured expected number of infections was less than 1.0. For NTSV, Sepsis Mortality, and Readmission this means the number of eligible cases was less than 1.0.

Program Status Measures:

- Yes ☐ No ❌ This hospital has a Maternity Safety Program in place. A maternity safety program provides a coordinated approach and emergency response to risks associated with pregnancy and childbirth.
- Yes ☐ No ❌ This hospital has a Sepsis Protocol in place. A Sepsis protocol provides guidance for a coordinated approach to identification and treatment of an infection or inflammatory response which is present throughout the body.
- Yes ☐ No ❌ This hospital has a Respiratory Monitoring program in place. Respiratory monitoring provides guidance for assessment of the risk of respiratory decline, and includes continuous monitoring of breathing and functioning of the lungs and circulatory system when indicated.

Outcome Measure Definitions:

- **CLABSI**: Central Line-Associated Bloodstream Infection: A serious infection that occurs when germs enter the bloodstream through a central line. A central line is a special intravenous (IV) that allows access to a major vein closer to the heart and can stay in place for weeks or months. The value shown above is a Standardized Infection Ratio (SIR), which is the ratio of observed-to-expected infections during the measure period. SIRs below 1.0 indicate that the observed number of infections during the measure period was lower than would be expected under normal conditions, whereas values above 1.0 indicate that the observed number of infections was higher than expected. Limitations: Some, but not all patient-specific risk factors are included in the adjustment of the SIR for these types of infections. However, not all relevant risk factors are included (e.g., trauma, emergency procedures). Hence, the SIR for hospitals that take care more medically complex or immunosuppressed patients may not be adequately adjusted to account for those patient-specific risk factors.

- **Colon SSI**: Colon-Surgical Site Infection: An infection (usually bacterial) that occurs after a person has colorectal surgery that occurs at the body site where the surgery took place. While some involve only the skin, others are more serious and can involve tissues under the skin, organs, or implanted material. The value shown above is a Standardized Infection Ratio (SIR), which is the ratio of observed-to-expected infections during the measure period. SIRs below 1.0 indicate that the observed number of infections during the measure period was lower than would be expected under normal conditions, whereas values above 1.0 indicate that the observed number of infections was higher than expected. Limitations: Some, but not all patient-specific risk factors are included in the adjustment of the SIR for these types of infections. However, not all relevant risk factors are included (e.g., trauma, emergency procedures). Hence, the SIR for hospitals performing more complex procedures or with larger volumes of trauma or emergency procedures may not be adequately adjusted to account for those patient-specific risk factors.

- **NTSV**: Nulliparous, Term, Singleton, Vertex Cesarean Birth Rate: The percentage of cesarean (surgical) births among first-time mothers who are at least 37 weeks pregnant with one baby in a head down position (not breech or transverse). Lower values indicate that fewer cesareans were performed in the hospital among primarily low-risk, first-time mothers. Limitations: NTSV rates do not take into account certain obstetric conditions, such as placenta previa, that may make Cesarean delivery the safer route for both mother and infant.

- **Sepsis Mortality**: Percent of patients, with a severe infection, who die in the hospital. Lower values indicate better survival. Limitations: Use of discharge/administrative data is limiting since such data has lower specificity for diagnosing than clinical data. In addition, without risk adjustment for differences in patient-specific factors, comparing rates among hospitals is difficult.

- **30-day Readmission - Hospital Wide All Cause 30-day Unplanned Readmission Rate**: The percentage of patients who were unexpectedly readmitted within 30 days of discharge from the hospital for any reason. Lower values indicate that fewer cases were unexpectedly readmitted after discharge. Limitations: Some, but not all patient-specific risk factors are included in the adjustment of the readmission rate. However, not all relevant risk factors are included (e.g., trauma, emergency procedures).
